Confirmatory Factor Analysis

Indicators Should Measure Common Construct

- Consider a dataset with variables for gender, ethnicity, and education

Indicators Should Measure Common Construct

- Consider a dataset with variables for gender, ethnicity, and education
- Would NOT want to specify a common factor “background” because

Indicators Should Measure Common Construct

- Consider a dataset with variables for gender, ethnicity, and education
- Would NOT want to specify a common factor “background” because
 - ① gender and ethnicity are unrelated; thus, could not measure common domain

Indicators Should Measure Common Construct

- Consider a dataset with variables for gender, ethnicity, and education
- Would NOT want to specify a common factor “background” because
 - ① gender and ethnicity are unrelated; thus, could not measure common domain
 - ② none of these indicators is ‘caused’ by some underlying ‘background’ factor

Indicators Should Measure Common Construct

- Consider a dataset with variables for gender, ethnicity, and education
- Would NOT want to specify a common factor “background” because
 - ① gender and ethnicity are unrelated; thus, could not measure common domain
 - ② none of these indicators is ‘caused’ by some underlying ‘background’ factor

How Many Indicators?

- Absolute minimum (with 2 or more factors) is 2 indicators / factor

How Many Indicators?

- Absolute minimum (with 2 or more factors) is 2 indicators / factor
- Advisable to have 3 or more indicators because of problems with identification, and it is difficult to estimate measurement error correlation

How Many Indicators?

- Absolute minimum (with 2 or more factors) is 2 indicators / factor
- Advisable to have 3 or more indicators because of problems with identification, and it is difficult to estimate measurement error correlation
- Kenny's (1979) rule of thumb: "Two *might* be fine, three is better, four is best, and anything more is gravy".

- Convergent validity: indicators have relatively high standardized factor loadings
Factor loadings $> .70$

- Convergent validity: indicators have relatively high standardized factor loadings
Factor loadings $> .70$
- Discriminant validity: estimated correlations between factors not excessively high
Correlations $< |.90|$

How Does CFA Differ from EFA?

- Exploratory factor analysis (EFA) is not SEM

How Does CFA Differ from EFA?

- Exploratory factor analysis (EFA) is not SEM
 - Considered an exploratory approach

How Does CFA Differ from EFA?

- Exploratory factor analysis (EFA) is not SEM
 - Considered an exploratory approach
 - NOT *a priori* (i.e., does not require specific hypotheses)

How Does CFA Differ from EFA?

- Exploratory factor analysis (EFA) is not SEM
 - Considered an exploratory approach
 - NOT *a priori* (i.e., does not require specific hypotheses)
 - All indicators are allowed to load on every factor

How Does CFA Differ from EFA?

- Exploratory factor analysis (EFA) is not SEM
 - Considered an exploratory approach
 - NOT *a priori* (i.e., does not require specific hypotheses)
 - All indicators are allowed to load on every factor
 - Identification occurs through infinite number of possible rotations
